C++ Overview

The C++ Language

cs.brown.edu

Data abstraction separates the interface (how the object is used) from the implementation (how it works Inside).

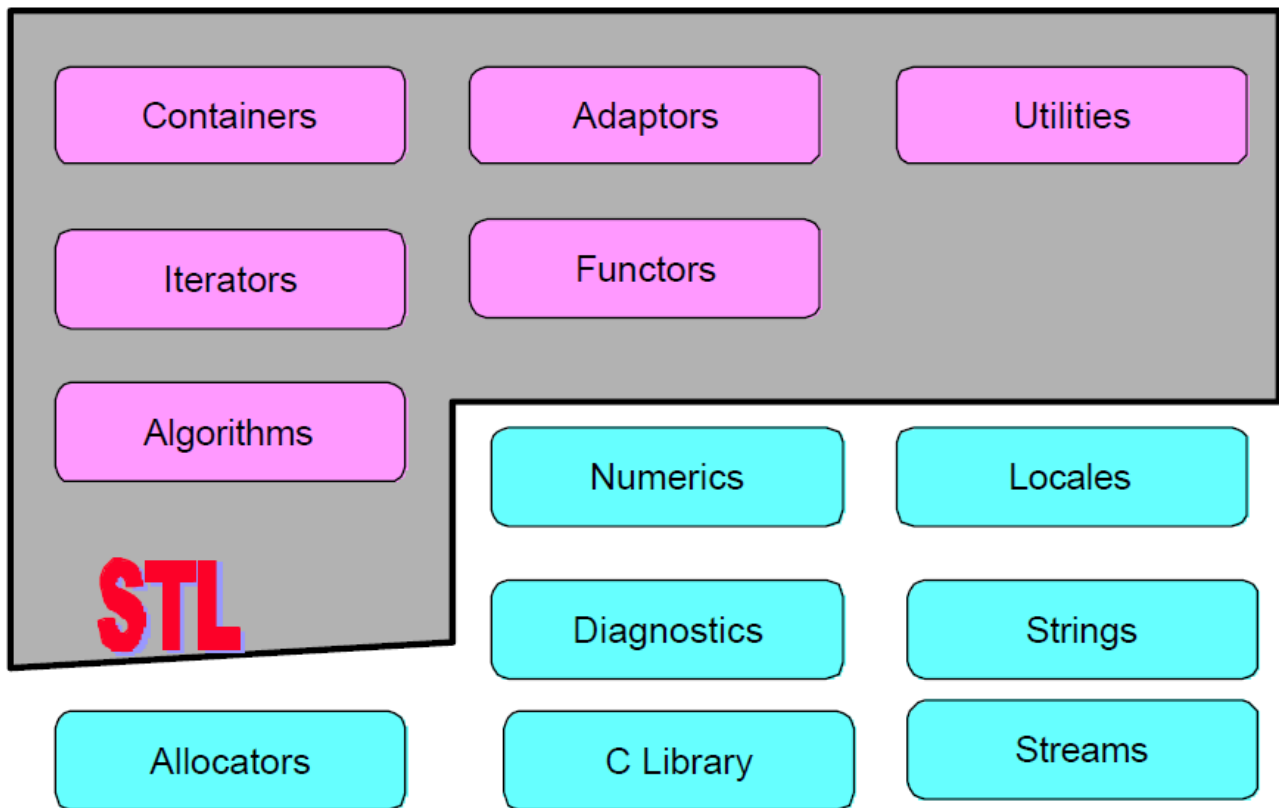

Relationships between objects and types are fundamental in object-oriented programming; inheritance defines a relationship between types corresponding to “is-a”, aggregation corresponds to “has-a”, and associations are more general relationships

Generic programming is a notion that has gained a lot of popularity in the last few years; originally used in Ada, the Standard Template Library (roughly a subset of the standard C++ library) made it popular in C++.

C++ with Standard Template Library

The C++ Standard Library

Containers are objects that contain other objects, e.g., vector, set, map.

2. Iterators represent locations in a container. Each container has its own iterator type.

3. Algorithms are operations on containers, e.g., find, sort, random_shuffle.

4. Functors are operations on objects, e.g., less, plus.

5. Adaptors are objects that change an interface, e.g., not1. (That's a one at the end, not an ell; there is also a not2.)

6. Utilities are components such as pairs, operations like comparison, etc. In the ANSI standard, allocators are included in the utilities section.

7. Diagnostics are provided to deal with exceptions.

8. Locales facilitate internationalization.

9. Numerics are container types that are optimized for speed, less general than containers, e.g., valarray, complex.

10. Strings replace C's character arrays.

11. Streams are used for input and output.

12. Allocators customize memory allocation, e.g., malloc_alloc.

History

The architecture of STL is largely the creation of one person, Alexander Stepanov.

In 1979 he began working out his initial ideas of generic programming and exploring their potential for revolutionizing software development. Although David Musser had developed and advocated some aspects of generic programming already by year 1971, it was limited to a rather specialized area of software development (computer algebra).

Stepanov recognized the full potential for generic programming and persuaded his then-colleagues at General Electric Research and Development (including, primarily, David Musser and Deepak Kapur) that generic programming should be pursued as a comprehensive basis for software development. At the time there was no real support in any programming language for generic programming.

The first major language to provide such support was Ada, with its generic units feature. By 1987 Stepanov and Musser had developed and published an Ada library for list processing that embodied the results of much of their research on generic programming.

The reason for turning to C++, which Stepanov was the C/C++ model of computation which allows very flexible access to storage via pointers is crucial to achieving generality without losing efficiency.

Stepanov experimented with many architectural and algorithm formulations, first in C and later in C++. Musser collaborated in this research and in 1992 Meng Lee joined Stepanov's project at HP and became a major contributor.

Andrew Koenig of Bell Labs had not become aware of the work and asked Stepanov to present the main ideas at a November 1993 meeting of the ANSI/ISO committee for C++ standardization. The committee's response was overwhelmingly favorable and led to a request from Koenig for a formal proposal in time for the March 1994 meeting.

Subsequently, the Stepanov and Lee document 17 was incorporated into the ANSI/ISO C++ draft standard (1, parts of clauses 17 through 27). It also influenced other parts of the C++ Standard Library, such as the string facilities, and some of the previously adopted standards in those areas were revised accordingly

The prospects for early widespread dissemination of STL were considerably improved with Hewlett-Packard's decision to make its implementation freely available on the Internet in August 1994. This implementation, developed by Stepanov, Lee, and Musser during the standardization process, became the basis of many implementations offered by compiler and library vendors today.

Overview - STL

The STL provides a ready-made set of common classes for C++,:

- containers and associative arrays,
- that can be used with any built-in type or with any user-defined type
- supports operations such as copying and assignment

STL algorithms are independent of **containers** - significantly reduces the complexity of the library. The STL achieves its results through the use of **templates**

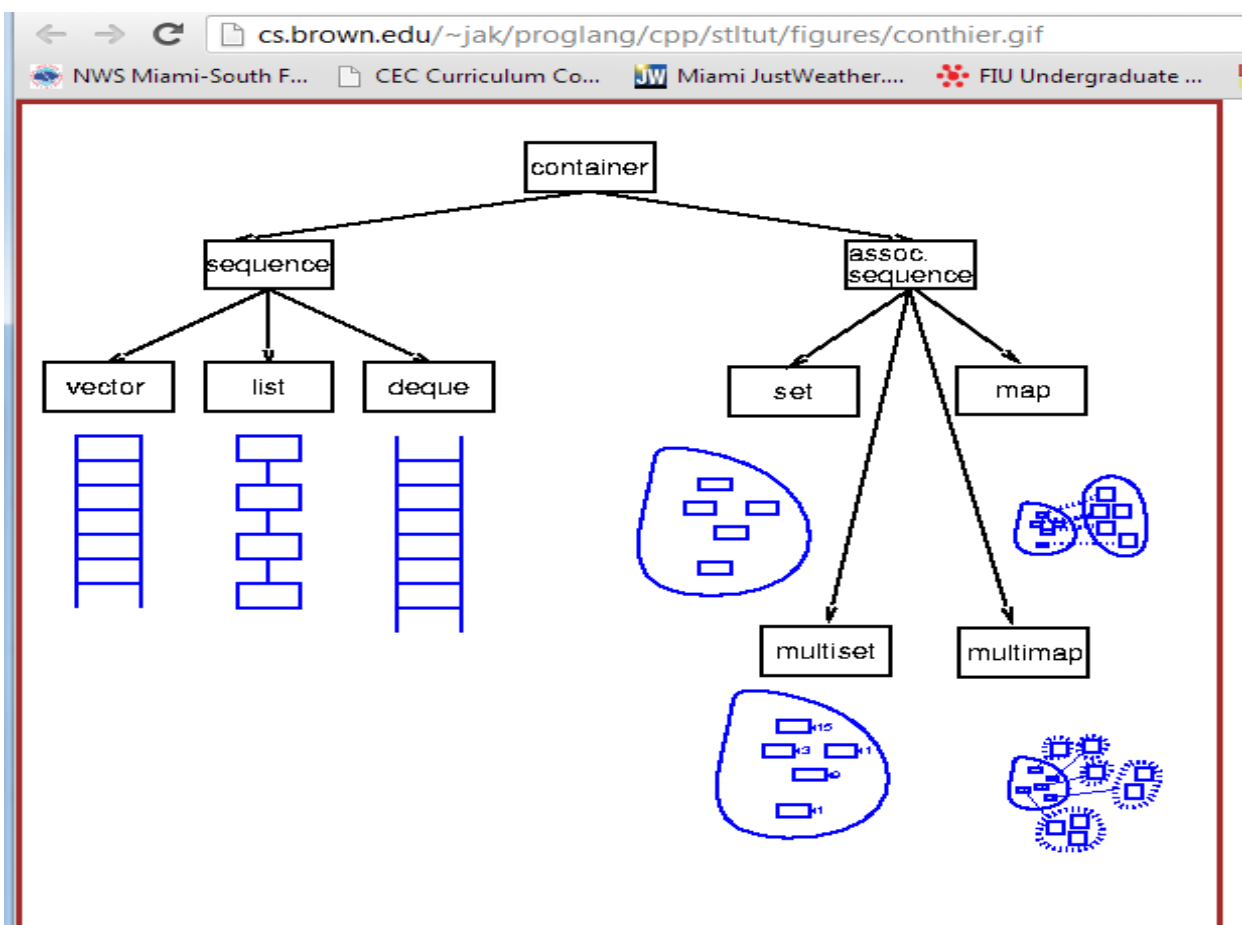

This approach provides

- compile-time polymorphism
- is often more efficient than traditional run-time polymorphism.

The STL was created as the first library of generic algorithms and data structures for C++, with four ideas in mind:

1. generic programming,
2. abstractness without loss of efficiency,
3. the Von Neumann computation model,
4. and value semantics.

http://www.thefullwiki.org/Standard_Template_Library

<http://cs.brown.edu/~jak/proglang/cpp/stltut/tut.html>

Overview containers, iterators, algorithms

STL provides a number of container types, representing objects that contain other objects.

One of these containers is a class called **vector** that behaves like an array, but can grow itself as necessary. One of the operations on vector is **push_back**, which pushes an element onto the end of the vector (growing it by one).

A vector contains a block of **contiguous** initialized elements -- if element index k has been initialized, then so have all the ones with indices less than k .

A vector can be **presized**, supplying the size at construction, and you can ask a vector how many elements it has with **size**. This is the **logical** number of elements -- the number of elements up to the highest-indexed one you have used. There is also a notion of **capacity** -- the number of elements the vector can hold before reallocating.

<http://cs.brown.edu/~jak/proglang/cpp/stltut/tut.html>

Iterators Preview

Iterators provide a way of specifying a position in a container.

An iterator can be **incremented** or **dereferenced**, and two iterators can be **compared**. There is a special iterator value called "past-the-end".

You can ask a vector for an iterator that points to the first element with the message **begin**. You can get a past-the-end iterator with the message **end**. The code

```
vector<int> v;  
// add some integers to v  
vector::iterator i1 = v.begin();  
vector::iterator i2 = v.end();
```

will create two iterators like this:

Operations like sort take two iterators to specify the source range.

To get the source elements, they increment and dereference the first iterator until it is equal to the second iterator. Note that this is a semi-open range: it includes the start but not the end.

Two vector iterators compare equal if they refer to the same element of the same vector.

Iterator Sort Example

Putting this together, here is the new program:

```
#include <string.h>
#include <algo.h>
#include <vector.h>
#include <stdlib.h>
#include <iostream.h>

main ()
{
    vector<int> v; // create an empty vector of integers
    int input;
    while (cin >> input)    // while not end of file
        v.push_back (input); // append to vector

    // sort takes two random iterators, and sorts the elements between
    // them. As is always the case in STL, this includes the value
    // referred to by first but not the one referred to by last; indeed,
    // this is often the past-the-end value, and is therefore not
    // dereferenceable.
    sort(v.begin(), v.end());

    int n = v.size();
    for (int i = 0; i < n; i++)
        cout << v[i] << "\n";
}
```

Iterator

<iterator>

Iterator definitions

In C++, an iterator is any object that, pointing to some element in a range of elements (such as an array or a [container](#)), has the ability to iterate through the elements of that range using a set of operators (at least, the increment (++) and dereference (*) operators).

The most obvious form of iterator is a *pointer*: A pointer can point to elements in an array, and can iterate through them using the increment operator (++). But other forms of iterators exist. For example, each [container](#) type (such as a [vector](#)) has a specific *iterator* type designed to iterate through its elements in an efficient way.

Notice that while a pointer is a form of iterator, not all iterators have the same functionality a pointer has; To distinguish between the requirements an iterator shall have for a specific algorithm, five different *iterator categories* exist:

Iterator categories

Iterators are classified in five categories depending on the functionality they implement:

In this graph, each iterator category implements the functionalities of all categories to its right:

[Input](#) and [output](#) iterators are the most limited types of iterators, specialized in performing only sequential input or output operations.

[Forward](#) iterators have all the functionality of [input](#) and [output](#) iterators, although they are limited to one direction in which to iterate through a range.

[Bidirectional](#) iterators can be iterated through in both directions. All [standard containers](#) support at least bidirectional iterators types.

[Random access](#) iterators implement all the functionalities of [bidirectional](#) iterators, plus, they have the ability to access ranges non-sequentially: offsets can be directly applied to these iterators without iterating through all the elements in between. This provides these iterators with the same functionality as standard pointers (pointers are iterators of this category).

<http://www.cplusplus.com/reference/iterator/>

The characteristics of each category of iterators are:

category				characteristic	valid expressions
all categories				Can be copied and copy-constructed	X b(a); b = a;
				Can be incremented	++a a++ *a++
Random Access	Bidirectional	Forward	Input	Accepts equality/inequality comparisons	a == b a != b
				Can be dereferenced as an <i>rvalue</i>	*a a->m
			Output	Can be dereferenced to be the left side of an assignment operation	*a = t *a++ = t
				Can be default-constructed	X a; X()
				Can be decremented	--a a-- *a--
				Supports arithmetic operators + and -	a + n n + a a - n a - b
				Supports inequality comparisons (<, >, <= and >=) between iterators	a < b a > b a <= b a >= b
				Supports compound assignment operations += and -=	a += n a -= n
				Supports offset dereference operator ([])	a[n]

Where X is an iterator type, a and b are objects of this iterator type, t is an object of the type pointed by the iterator type, and n is an integer value.

Random access iterators have all characteristics. Bidirectional iterators have a subset of random access iterators's. Forward iterators have a subset of bidirectional iterators's. And input and output have each their own subset of forward iterator's.

Iterator Classes

Primitives

iterator	the basic iterator (class template)
input_iterator_tag	
output_iterator_tag	
forward_iterator_tag	empty class types used to indicate iterator categories (class)
bidirectional_iterator_tag	
random_access_iterator_tag	
iterator_traits	provides uniform interface to the properties of an iterator (class template)

Adaptors

reverse_iterator	iterator adaptor for reverse-order traversal (class template)
move_iterator (C++11)	iterator adaptor which dereferences to an rvalue reference (class template)
back_insert_iterator	iterator adaptor for insertion at the end of a container (class template)
front_insert_iterator	iterator adaptor for insertion at the front of a container (class template)
insert_iterator	iterator adaptor for insertion into a container (class template)

Stream Iterators

istream_iterator	input iterator that reads from <code>std::basic_istream</code> (class template)
ostream_iterator	output iterator that writes to <code>std::basic_ostream</code> (class template)
istreambuf_iterator	input iterator that reads from <code>std::basic_streambuf</code> (class template)
ostreambuf_iterator	output iterator that writes to <code>std::basic_streambuf</code> (class template)

Functions *Adaptors*

make_move_iterator (C++11)	creates a <code>std::move_iterator</code> of type inferred from the argument (function template)
front_inserter	creates a <code>std::front_insert_iterator</code> of type inferred from the argument (function template)
back_inserter	creates a <code>std::back_insert_iterator</code> of type inferred from the argument (function template)
inserter	creates a <code>std::insert_iterator</code> of type inferred from the argument (function template)

Functions *Operations*

advance	advances an iterator by given distance (function)
distance	returns the distance between two iterators (function)
next (C++11)	increment an iterator (function)
prev (C++11)	decrement an iterator (function)
Range	
begin (C++11)	returns an iterator to the beginning of a container or array (function)
end (C++11)	returns an iterator to the end of a container or array (function)

Non-member operators

operator== operator!= operator< operator<= operator> operator>=	compares the underlying iterators (function template)
operator+	advances the iterator (function template)
operator-	computes the distance between two iterator adaptors (function template)

operator==operator!=operator<operator<=operator>operator>=

compares the underlying iterators

(function template)

operator+

advances the iterator

(function template)

operator-

computes the distance between two iterator adaptors

(function template)

operator==

compares two istream_iterators

operator!=

(function template)

operator==

compares two istreambuf_iterators

operator!=

(function template)

Iterators Example

<http://www.yolinux.com/TUTORIALS/LinuxTutorialC++STL.html>

```
#include <iostream>
#include <vector>
#include <string>

using namespace std;

main()
{
    vector<string> SS;

    SS.push_back("The number is 10");
    SS.push_back("The number is 20");
    SS.push_back("The number is 30");

    cout << "Loop by index:" << endl;

    int ii;
    for(ii=0; ii < SS.size(); ii++)
    {
        cout << SS[ii] << endl;
    }

    cout << endl << "Constant Iterator:" << endl;

    vector<string>::const_iterator cii;
    for(cii=SS.begin(); cii!=SS.end(); cii++)
    {
        cout << *cii << endl;
    }

    cout << endl << "Reverse Iterator:" << endl;

    vector<string>::reverse_iterator rii;
    for(rii=SS.rbegin(); rii!=SS.rend(); ++rii)
    {
        cout << *rii << endl;
    }

    cout << endl << "Sample Output:" << endl;

    cout << SS.size() << endl;
    cout << SS[2] << endl;

    swap(SS[0], SS[2]);
    cout << SS[2] << endl;
}
```

Iterator adaptors

In addition to iterating through containers, iterators can iterate over streams, either to read elements or to write them.

An input stream like *cin* has the right functionality for an input iterator:

- it provides access to a sequence of elements.

The trouble is, it has the wrong interface for an iterator:

- operations that use iterators expect to be able to increment them and dereference them.

STL provides **adaptors**, types that transform the interface of other types. This is very much how electrical adaptors work.

One very useful adaptor is `istream_iterator`.

This is a template type; you parameterize it by the **type** of object you want to read from the stream. i.e. `int`, `char`, `float`, etc..

`istream_iterator`

In this case we want integers, so we would use an `istream_iterator<int>`.

- `Istream` iterators are initialized by giving them a stream
- dereferencing the iterator reads an element from the stream,
- incrementing the iterator has no effect.

An `istream` iterator that is created with the default constructor:

- has the past-the-end value,

as does an iterator whose stream has reached the end of file.

Iterator Adaptor Example

```
// include library for each feature used HW
// cppreference.com

#include <algorithm> // sort
#include <vector>    // vector
#include <iostream>  //cin cout
#include <iterator>  //iterators

int main ()
{
    using namespace std;

    // create a vector to hold numbers typed in
    vector<int> v;
    cout << "Please enter numbers (ctrl-D) ends sequence" << endl;
    istream_iterator<int> start (cin); //input iterator from stream
    istream_iterator<int> end;    // end of stream iterator
    back_inserter_iterator<vector<int> > dest (v); // append integers to vector

    copy (start, end, dest); // copy cin numbers to vector
    sort(v.begin(), v.end()); // sort the vector
    copy (v.begin(), v.end(), ostream_iterator<int>(cout, "\n")); // copy vector to cout

    return 0;
}
```

the vector is

- copied into memory,
- sorted, and
- copied out again.

Templates

Are a feature of the C++ programming language that allow functions and classes to operate with generic types.

- char
- int
- float
- double
- structure
- class

This allows a function or class to work on many different data types without being rewritten for each one.

Templates are of great utility to programmers in C++, especially when combined with multiple inheritance and operator overloading.

The C++ Standard Library provides many useful functions within a framework of connected templates.

[http://www.thefullwiki.org/Template_\(programming\)](http://www.thefullwiki.org/Template_(programming))

Defining a Template

Imagine that we want to write a function to compare two values and indicate whether the first is less than, equal to, or greater than the second.

In practice, we'd want to define several such functions, each of which will compare values of a given type.

Our first attempt might be to define several overloaded functions:

```
// returns 0 if the values are equal, -1 if v1 is smaller, 1 if v2 is smaller
int compare(const string &v1, const string &v2)
{
    if (v1 < v2) return -1;
    if (v2 < v1) return 1;
    return 0;
}
int compare(const double &v1, const double &v2)
{
    if (v1 < v2) return -1;
    if (v2 < v1) return 1;
    return 0;
}
```

These functions are nearly identical: The only difference between them is the type of their parameters.

The function body is the same in each function.

Having to repeat the body of the function for each type that we compare is tedious and error-prone.

More importantly, we need to know when we write the program all the types that we might ever want to compare. This strategy cannot work if we want to be able to use the function on types that our users might supply.

Rather than defining a new function for each type, we can define a function **template**.

A function template is a formula from which we can generate **type-specific** versions of that function.

The template version of compare looks like

Function Template Definition Example

```
template <typename T>
int compare(const T &v1, const T &v2)
{
    if (v1 < v2) return -1;
    if (v2 < v1) return 1;
    return 0;
}
```

A **template definition** starts with the

keyword template followed by a

template parameter list,

which is a comma-separated list of one or more template parameters bracketed by the less-than (<) and greater-than (>) tokens.

Our compare function declares one type parameter named T.

Inside compare, we use the name T to refer to a type.

Which actual type T represents is determined at compile time based on how compare is used.

Function templates Example

```
1. #include <iostream> // cin, cout, endl
2.
3. using std::cout;
4. using std::endl;
5. using std::string;
6.
7. template <typename T>
8. const T& max(const T& x, const T& y)
9. {
10.     if(y < x)
11.         return x;
12.     return y;
13. }
14.
15. int main()
16. {
17.
18.     // This will call max <int> (by argument deduction)
19.     cout << max(3, 7) << endl;
20.     // This will call max<double> (by argument deduction)
21.     cout << max(3.0, 4.0) << endl;
22.     // This type is ambiguous; explicitly instantiate max<double>
23.     cout << max<double>(3, 8.0) << endl;
24.     // This type is character by explicit instantiation
25.     cout << max<char>('A', 'C') << endl;
26.
27.
28.     return 0;
29. }
```

- In 19 and 21, the template argument T is automatically deduced by the compiler to be int and double, respectively.
- In 23, case deduction fails because the type of the parameters must in general exactly match the template arguments.
- This function template can be instantiated with any copy-constructible type for which the expression (y < x) is valid.
- **For user-defined types, this implies that the less-than operator must be overloaded.**

Function Template Variations Example

```
// function template variations
#include <vector>
#include <iterator>
#include <iostream>
#include <cmath>
#include <string>
#include <utility>
#include <cstring>
using std::vector;
using std::cout;
using std::endl;
using std::string;
using std::iter_swap;

template <typename T>
void myReverse(T& input)
{
    typename T::iterator it;
    typename T::iterator et;
    for (it=input.begin(), et=input.end(); it< et; it++, et--)
        { iter_swap(it, et-1); }
    return;
}

template <typename T>
void showContents(T& input)
{
    typename T::iterator it;
    for (it=input.begin(); it != input.end(); it++)
        { cout << *it << " "; }
    cout << endl;
}

int main()
{
    int x[] = {1, 2, 3, 4, 5};
    vector<int> MyVec(x, x+5);
    showContents(MyVec);
    myReverse(MyVec);
    showContents(MyVec);

    string MyString ("This is my C++ string");
    showContents(MyString);
    myReverse(MyString);
    showContents(MyString);

    string str = "This is a C string";
    vector<char> data(str.begin(), str.end());
    showContents(data);
    myReverse(data);
    showContents(data);

    vector<string> fruit;
    fruit.push_back("apple");
    fruit.push_back("banana");
    fruit.push_back("orange");
    fruit.push_back("strawberry");
    showContents((fruit));
    myReverse(fruit);
    showContents((fruit));
}
```

Class templates

A class template provides a specification for generating classes based on parameters.

Class templates are commonly used to implement **containers**.

A class template is instantiated by passing a given set of types to it as template arguments.

The C++ Standard Library contains many class templates, in particular the containers adapted from the Standard Template Library, such as vector.

The basic syntax for declaring a templated class is as follows:

```
template <class a_type>
class a_class {...};
```

The keyword 'class' above simply means that the identifier a_type will stand for a datatype.

Note: a_type is not a keyword; it is an identifier that during the execution of the program will represent a single datatype. For example, you could, when defining variables in the class, use the following line:

```
a_type a_var;
```

and when the programmer defines which datatype 'a_type' is to be when the program instantiates a particular instance of a_class, a_var will be of that type.

When declaring an instance of a templated class, the syntax is as follows:

```
a_class<int> an_example_class;
```

Class Template Example

```
// class templates
#include <iostream>
using namespace std;

template <class T>
class mypair {
    T a, b;
public:
    mypair (T first, T second)
        {a=first; b=second;}
    T getmax ();
};

template <class T>
T mypair<T>::getmax ()
{
    T retval;
    retval = a>b? a : b;
    return retval;
}

int main () {
    mypair <int> myobject (100, 75);
    cout << myobject.getmax();
    return 0;
}
```

introducing the vector template

```
// vect1.cpp -- introducing the vector template HW
#include <iostream>
#include <string>
#include <vector>
#define NUM 5
int main()
{
    using std::vector;
    using std::string;
    using std::cin;
    using std::cout;
    using std::endl;

    vector<int> ratings(NUM);
    vector<string> titles(NUM);
    cout << "You will do exactly as told. You will enter"
    << NUM << " book titles and your ratings (0-10).\n";

    int i;
    for (i = 0; i < NUM; i++)
    {
        cout << "Enter title #" << i + 1 << ": ";
        getline(cin,titles[i]);
        cout << "Enter your rating (0-10): ";
        cin >> ratings[i];
        cin.get();
    }
    cout << "Thank you. You entered the following:\n"
    << "Rating\tBook\n";

    for (i = 0; i < NUM; i++)
    {
        cout << ratings[i] << "\t" << titles[i] << endl;
    }
    return 0;
}
```

STL components

Containers

Containers are objects that conceptually contain other objects.

They use certain basic properties of the objects (ability to copy, etc.) but otherwise do not depend on the type of object they contain.

STL containers may contain pointers to objects, though in this case you will need to do a little extra work.

vectors, lists, dequeues, sets, multisets, maps, multimaps, queues, stacks, and priority queues, are all provided.

Perhaps more importantly,

- built-in containers (C arrays) and
- user-defined containers

can also be used as STL containers;.

This is generally useful when applying operations to the containers, e.g., sorting a container.

Using user-defined types as STL containers can be accomplished by satisfying the requirements listed in the STL [container requirements definition](#).

If this is not feasible, you can define an [adaptor class](#) that changes the interface to satisfy the requirements.

All the types are "templated", of course,

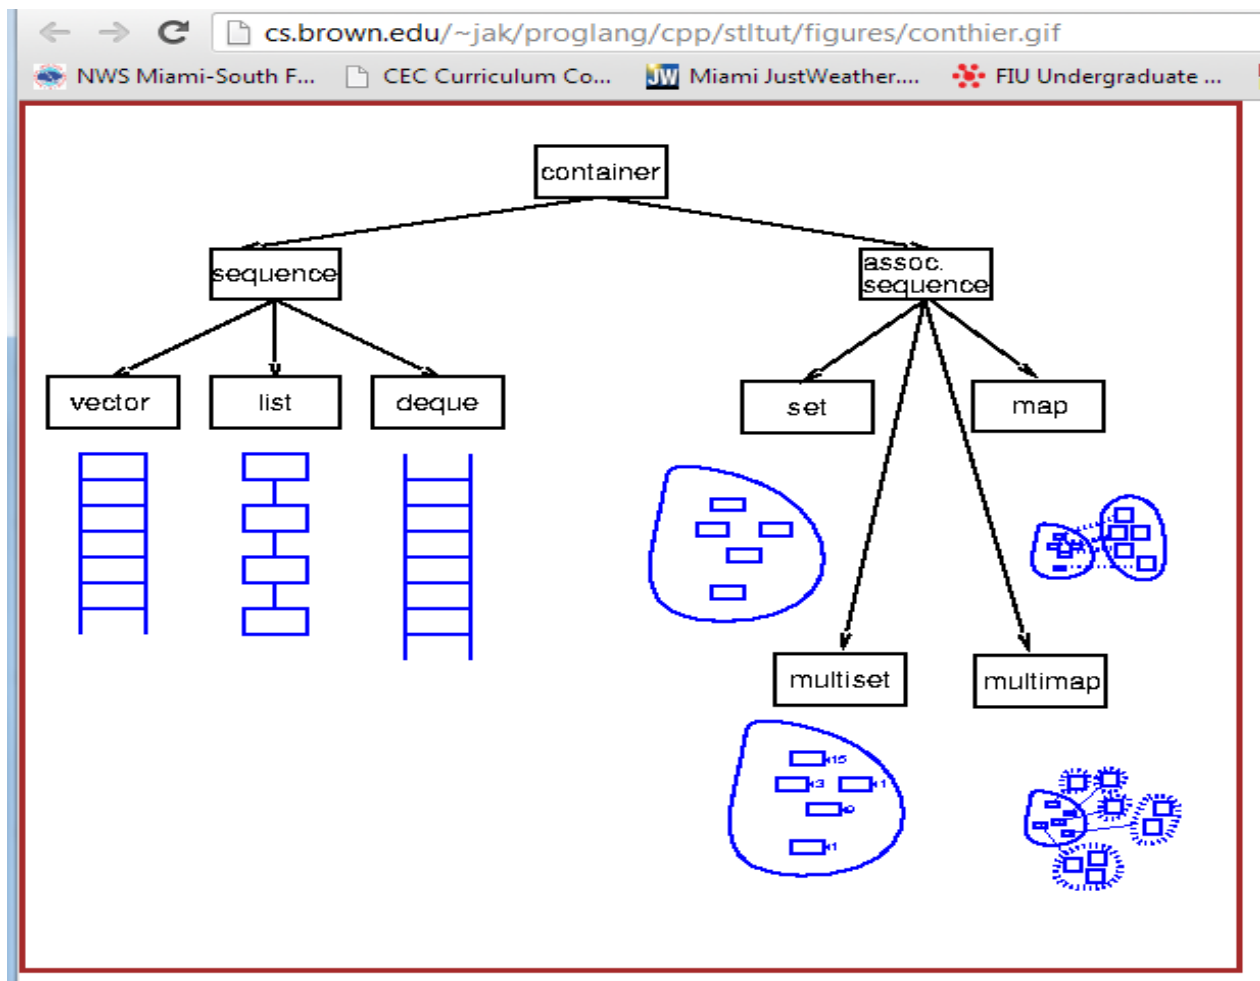

so you can have a vector of ints

or Windows

or a vector of vector of sets of multimaps of strings to Students.

Sweat, compiler-writers, sweat! - Make the compiler do the work.

Hierarchy

Sequences

Contiguous blocks of objects; you can insert elements at any point in the sequence, but the performance will depend on the type of sequence and where you are inserting.

Vectors

Fast insertion at end, and allow random access.

Lists

Fast insertion anywhere, but provide only sequential access.

Deque

Fast insertion at either end, and allow random access. Restricted types, such as stack and queue, are built from these using [adaptors](#).

Stacks and queues

Provide restricted versions of these types, in which some operations are not allowed.

Associative containers

Associative containers are a generalization of sequences. Sequences are indexed by integers; associative containers can be indexed by any type.

The most common type to use as a key is a string; you can have a set of strings, or a map from strings to employees, and so forth.

It is often useful to have other types as keys; for example, if I want to keep track of the names of all the Widgets in an application, I could use a map from Widgets to Strings.

Sets

Sets allow you to add and delete elements, query for membership, and iterate through the set.

Multisets

Multisets are just like sets, except that you can have several copies of the same element (these are often called bags).

Maps

Maps represent a mapping from one type (the *key* type) to another type (the *value* type). You can associate a value with a key, or find the value associated with a key, very efficiently; you can also iterate through all the keys.

Multimaps

Multimaps are just like maps except that a key can be associated with several values.

other containers:

priority queue,

bit vector,

queue

Example using container algorithms

Here is a program that generates a random permutation of the first *n* integers, where **n** is specified on the command line.

```
#include <iostream.h>
#include <vector.h>
#include <algo.h>
#include <iterator.h>

main (int argc, char *argv[])
{
    int n = atoi (argv[1]); // argument checking removed for clarity

    vector<int> v;
    for (int i = 0; i < n; i++)          // append integers 0 to n-1 to v
        v.push_back (i);

    random_shuffle (v.begin(), v.end());           // shuffle
    copy (v.begin(), v.end(), ostream_iterator<int> (cout, "\n")); // print
}
```

This program creates an empty vector and fills it with the integers from 0 to **n**. It then shuffles the vector and prints it out.

Container Summary Table

Simple Containers

Container	Description
Simple Containers	
pair	The pair container is a simple associative container consisting of a 2-tuple of data elements or objects, called 'first' and 'second', in that fixed order. The STL 'pair' can be assigned, copied and compared. The array of objects allocated in a map or hash_map (described below) are of type 'pair' by default, where all the 'first' elements act as the unique keys, each associated with their 'second' value objects.
Sequences (Arrays / Linked Lists) - ordered collections	
vector	a dynamic array, like C array (i.e., capable of random access) with the ability to resize itself automatically when inserting or erasing an object. Inserting and removing an element to/from back of the vector at the end takes amortized constant time. Inserting and erasing at the beginning or in the middle is linear in time. A specialization for type bool exists, which optimizes for space by storing bool values as bits.
list	a doubly-linked list; elements are not stored in contiguous memory. Opposite performance from a vector. Slow lookup and access (linear time), but once a position has been found, quick insertion and deletion (constant time).
deque (double ended queue)	a vector with insertion/erase at the beginning or end in amortized constant time, however lacking some guarantees on iterator validity after altering the deque.

Container Adaptors

Container	Description
Container adaptors	
queue	Provides FIFO queue interface in terms of <code>push/pop/front/back</code> operations. Any sequence supporting operations <code>front()</code> , <code>back()</code> , <code>push_back()</code> , and <code>pop_front()</code> can be used to instantiate <code>queue</code> (e.g. <code>list</code> and <code>deque</code>).
priority_queue	Provides priority queue interface in terms of <code>push/pop/top</code> operations (the element with the highest priority is on top). Any random-access sequence supporting operations <code>front()</code> , <code>push_back()</code> , and <code>pop_back()</code> can be used to instantiate <code>priority_queue</code> (e.g. <code>vector</code> and <code>deque</code>). Elements should additionally support comparison (to determine which element has a higher priority and should be popped first).
stack	Provides LIFO stack interface in terms of <code>push/pop/top</code> operations (the last-inserted element is on top). Any sequence supporting operations <code>back()</code> , <code>push_back()</code> , and <code>pop_back()</code> can be used to instantiate <code>stack</code> (e.g. <code>vector</code> , <code>list</code> , and <code>deque</code>).

Containers – Associative and other types

Container	Description
Associative containers - unordered collections	
set	a mathematical set ; inserting/erasing elements in a set does not invalidate iterators pointing in the set. Provides set operations union , intersection , difference , symmetric difference and test of inclusion. Type of data must implement comparison operator < or custom comparator function must be specified. Implemented using a self-balancing binary search tree .
multiset	same as a set, but allows duplicate elements.
map	an associative array ; allows mapping from one data item (a key) to another (a value). Type of key must implement comparison operator < or custom comparator function must be specified. Implemented using a self-balancing binary search tree.
multimap	same as a map, but allows duplicate keys.
hash_set hash_multiset hash_map hash_multimap	similar to a set, multiset, map, or multimap, respectively, but implemented using a hash table ; keys are not ordered, but a hash function must exist for the key type. These containers are not part of the C++ Standard Library, but are included in SGI's STL extensions, and are included in common libraries such as the GNU C++ Library in the <code>__gnu_cxx</code> namespace. These are scheduled to be added to the C++ standard as part of TR1 , with the slightly different names of <code>unordered_set</code> , <code>unordered_multiset</code> , <code>unordered_map</code> and <code>unordered_multimap</code> .
Other types of containers	
bitset	stores series of bits similar to a fixed-sized vector of bools. Implements bitwise operations and lacks iterators. Not a Sequence.
valarray	another C-like array like vector, but is designed for high speed numerics at the expense of some programming ease and general purpose use. It has many features that make it ideally suited for use with vector processors in traditional vector supercomputers and SIMD units in consumer-level scalar processors, and also ease vector mathematics programming even in scalar computers.

Algorithms

algorithm: Routines to find, count, sort, search, ... elements in container classes

A large number of algorithms to perform operations such as searching and sorting are provided in the STL,

each implemented to require a certain level of iterator (and therefore will work on any container which provides an interface by iterators).

Algorithms library

C++

Algorithm library

The algorithms library defines functions for a variety of purposes (e.g. searching, sorting, counting, manipulating) that operate on ranges of elements. Note that a range is defined as `[first, last)` where `last` refers to the element *past* the last element to inspect or modify.

Non-modifying sequence operations

Defined in header `<algorithm>`

all_of
any_of
none_of

(C++11)

(C++11)

(C++11)

checks if a predicate is `true` for all, any or none of the elements in a range

(function template)

for_each

applies a function to a range of elements

(function template)

count
count_if

returns the number of elements satisfying specific criteria

(function template)

mismatch

finds the first position where two ranges differ

(function template)

equal

determines if two sets of elements are the same

(function template)

find
find_if
find_if_not

finds the first element satisfying specific criteria

(function template)

(C++11)

find_end

finds the last sequence of elements in a certain range

(function template)

find_first_of	searches for any one of a set of elements (function template)
adjacent_find	finds two identical (or some other relationship) items adjacent to each other (function template)
search	searches for a range of elements (function template)
search_n	searches for a number consecutive copies of an element in a range (function template)

Modifying sequence operations

Defined in header `<algorithm>`

copy copy_if (C++11)	copies a range of elements to a new location (function template)
copy_n (C++11)	copies a number of elements to a new location (function template)
copy_backward	copies a range of elements in backwards order (function template)
move (C++11)	moves a range of elements to a new location (function template)
move_backward (C++11)	moves a range of elements to a new location in backwards order (function template)
fill	assigns a range of elements a certain value (function template)
fill_n	assigns a value to a number of elements (function template)
transform	applies a function to a range of elements (function template)
generate	saves the result of a function in a range (function template)
generate_n	saves the result of N applications of a function (function template)
remove remove_if	removes elements satisfying specific criteria (function template)
remove_copy remove_copy_if	copies a range of elements omitting those that satisfy specific criteria (function template)
replace replace_if	replaces all values satisfying specific criteria with another value (function template)

<u>replace_copy</u>	copies a range, replacing elements satisfying specific criteria with another value
<u>replace_copy_if</u>	(function template)
swap	swaps the values of two objects
	(function template)
swap_ranges	swaps two ranges of elements
	(function template)
iter_swap	swaps the elements pointed to by two iterators
	(function template)
reverse	reverses the order elements in a range
	(function template)
reverse_copy	creates a copy of a range that is reversed
	(function template)
rotate	rotates the order of elements in a range
	(function template)
rotate_copy	copies and rotate a range of elements
	(function template)
random_shuffle	
shuffle	randomly re-orders elements in a range
	(function template)
(C++11)	
unique	removes consecutive duplicate elements in a range
	(function template)
unique_copy	creates a copy of some range of elements that contains no consecutive duplicates
	(function template)

Partitioning operations

Defined in header `<algorithm>`

is_partitioned	determines if the range is partitioned by the given predicate
(C++11)	(function template)
partition	divides a range of elements into two groups
	(function template)
partition_copy	copies a range dividing the elements into two groups
(C++11)	(function template)
stable_partition	divides elements into two groups while preserving their relative order
	(function template)
partition_point	locates the partition point of a partitioned range
(C++11)	(function template)

Sorting operations (on sorted ranges)

Defined in header `<algorithm>`

is_sorted (C++11)	checks whether a range is sorted into ascending order (function template)
is_sorted_until (C++11)	finds the largest sorted subrange (function template)
sort	sorts a range into ascending order (function template)
partial_sort	sorts the first N elements of a range (function template)
partial_sort_copy	copies and partially sorts a range of elements (function template)
stable_sort	sorts a range of elements while preserving order between equal elements (function template)
nth_element	partially sorts the given range making sure that it is partitioned by the given element (function template)

Binary search operations (on sorted ranges)

Defined in header `<algorithm>`

lower_bound	returns an iterator to the first element <i>not less</i> than the given value (function template)
upper_bound	returns an iterator to the first element <i>greater</i> than a certain value (function template)
binary_search	determines if an element exists in a certain range (function template)
equal_range	returns range of elements matching a specific key (function template)

Set operations (on sorted ranges)

Defined in header `<algorithm>`

merge	merges two sorted ranges (function template)
inplace_merge	merges two ordered ranges in-place (function template)
includes	returns true if one set is a subset of another (function template)
set_difference	computes the difference between two sets (function template)
set_intersection	computes the intersection of two sets (function template)

set_symmetric_difference computes the symmetric difference between two sets
(function template)

set_union computes the union of two sets
(function template)

Heap operations

Defined in header `<algorithm>`

is_heap checks if the given range is a heap
(function template)

is_heap_until finds the largest subrange that is heap
(C++11)
(function template)

make_heap creates a heap out of a range of elements
(function template)

push_heap adds an element to a heap
(function template)

pop_heap removes the largest element from a heap
(function template)

sort_heap turns a heap into a sorted range of elements
(function template)

Minimum/maximum operations

Defined in header `<algorithm>`

max returns the larger of two elements
(function template)

max_element returns the largest element in a range
(function template)

min returns the smaller of two elements
(function template)

min_element returns the smallest element in a range
(function template)

minmax returns the larger and the smaller of two elements
(C++11)
(function template)

minmax_element returns the smallest and the largest element in a range
(C++11)
(function template)

lexicographical_compare returns true if one range is lexicographically less than another
(function template)

is_permutation determines if a sequence is a permutation of another sequence
(C++11)
(function template)

next_permutation generates the next greater lexicographic permutation of a range of elements
(function template)

of elements
(function template)

Numeric operations

Defined in header `<numeric>`

iota
(C++11) fills a range with successive increments of the starting value
(function template)

accumulate
sums up a range of elements
(function template)

inner_product
computes the inner product of two ranges of elements
(function template)

adjacent_difference
computes the differences between adjacent elements in a range
(function template)

partial_sum
computes the partial sum of a range of elements
(function template)

C library

Defined in header `<cstdlib>`

qsort
sorts a range of elements with unspecified type
(function)

bsearch
searches an array for an element of unspecified type
(function)

Functors

The STL includes classes that overload the function operator (operator())

They are useful for keeping and retrieving state information in functions passed into other functions.

Function objects (aka "functors"). Functors are objects that can be treated as though they are a function or function pointer--you could write code that looks like this:

```
1 myFunctorClass functor;  
2 functor( 1, 2, 3 );
```

This code works because C++ allows you to [overload](#) operator(), the "function call" operator. The function call operator can take any number of arguments of any types and return anything it wishes to. (It's probably the most flexible operator that can be overloaded)

```
#include <iostream>

class myFunctorClass
{
public:
    myFunctorClass (int x) : _x( x ) {}
    int operator() (int y) { return _x + y; } //<<<<<<<<<<<
private:
    int _x;
};

int main()
{
    myFunctorClass addFive( 5 );
    std::cout << addFive( 6 );

    return 0;
}
```
