Greedy Algorithms | Set 7 (Dijkstra's shortest path algorithm)

Given a graph and a source vertex in graph, find shortest paths from source to all vertices in the given graph.

Dijkstra's algorithm is very similar to [Prim's algorithm for minimum spanning tree](#). Like Prim's MST, we generate a *SPT (shortest path tree)* with given source as root. We maintain two sets, one set contains vertices included in shortest path tree, other set includes vertices not yet included in shortest path tree. At every step of the algorithm, we find a vertex which is in the other set (set of not yet included) and has minimum distance from source.

Below are the detailed steps used in Dijkstra's algorithm to find the shortest path from a single source vertex to all other vertices in the given graph.

Algorithm

- 1) Create a set *sptSet* (shortest path tree set) that keeps track of vertices included in shortest path tree, i.e., whose minimum distance from source is calculated and finalized. Initially, this set is empty.
- 2) Assign a distance value to all vertices in the input graph. Initialize all distance values as INFINITE. Assign distance value as 0 for the source vertex so that it is picked first.
- 3) While *sptSet* doesn't include all vertices
 -a) Pick a vertex *u* which is not there in *sptSet* and has minimum distance value.
 -b) Include *u* to *sptSet*.
 -c) Update distance value of all adjacent vertices of *u*. To update the distance values, iterate through all adjacent vertices. For every adjacent vertex *v*, if sum of distance value of *u* (from source) and weight of edge *u-v*, is less than the distance value of *v*, then update the distance value of *v*.

Let us understand with the following example:

The set *sptSet* is initially empty and distances assigned to vertices are {0, INF, INF, INF, INF, INF, INF, INF, INF} where INF indicates infinite. Now pick the vertex with minimum distance value. The vertex 0 is picked, include it in *sptSet*. So *sptSet* becomes {0}. After including 0 to *sptSet*, update distance values of its adjacent vertices. Adjacent vertices of 0 are 1 and 7. The distance values of 1 and 7 are updated as 4 and 8. Following subgraph shows vertices and their distance values, only the vertices with finite distance values are shown. The vertices included in SPT are shown in green color.

Pick the vertex with minimum distance value and not already included in SPT (not in *sptSet*). The vertex 1 is picked and added to *sptSet*. So *sptSet* now becomes {0, 1}. Update the distance values of adjacent vertices of 1. The distance value of vertex 2 becomes 12.

Pick the vertex with minimum distance value and not already included in SPT (not in *sptSet*). Vertex 7

is picked. So $sptSet$ now becomes $\{0, 1, 7\}$. Update the distance values of adjacent vertices of 7. The distance value of vertex 6 and 8 becomes finite (15 and 9 respectively).

Pick the vertex with minimum distance value and not already included in SPT (not in $sptSet$). Vertex 6 is picked. So $sptSet$ now becomes $\{0, 1, 7, 6\}$. Update the distance values of adjacent vertices of 6. The distance value of vertex 5 and 8 are updated.

We repeat the above steps until $sptSet$ doesn't include all vertices of given graph. Finally, we get the following Shortest Path Tree (SPT).

How to implement the above algorithm?

We use a boolean array $sptSet[]$ to represent the set of vertices included in SPT. If a value $sptSet[v]$ is true, then vertex v is included in SPT, otherwise not. Array $dist[]$ is used to store shortest distance values of all vertices.

// A C / C++ program for Dijkstra's single source shortest path algorithm.
// The program is for adjacency matrix representation of the graph

```
#include <stdio.h>
#include <limits.h>
```

```
// Number of vertices in the graph
#define V 9
```

```
// A utility function to find the vertex with minimum distance value, from
// the set of vertices not yet included in shortest path tree
int minDistance(int dist[], bool sptSet[])
```

```

{
    // Initialize min value
    int min = INT_MAX, min_index;

    for (int v = 0; v < V; v++)
        if (sptSet[v] == false && dist[v] <= min)
            min = dist[v], min_index = v;

    return min_index;
}

// A utility function to print the constructed distance array
int printSolution(int dist[], int n)
{
    printf("Vertex   Distance from Source\n");
    for (int i = 0; i < V; i++)
        printf("%d \t\t %d\n", i, dist[i]);
}

// Function that implements Dijkstra's single source shortest path algorithm
// for a graph represented using adjacency matrix representation
void dijkstra(int graph[V][V], int src)
{
    int dist[V];           // The output array. dist[i] will hold the shortest
                          // distance from src to i

    bool sptSet[V]; // sptSet[i] will true if vertex i is included in shortest
                  // path tree or shortest distance from src to i is final

    // Initialize all distances as INFINITE and sptSet[] as false
    for (int i = 0; i < V; i++)
        dist[i] = INT_MAX, sptSet[i] = false;

    // Distance of source vertex from itself is always 0
    dist[src] = 0;

    // Find shortest path for all vertices
    for (int count = 0; count < V-1; count++)
    {
        // Pick the minimum distance vertex from the set of vertices not
        // yet processed. u is always equal to src in first iteration.
        int u = minDistance(dist, sptSet);

        // Mark the picked vertex as processed
        sptSet[u] = true;

        // Update dist value of the adjacent vertices of the picked vertex.
        for (int v = 0; v < V; v++)

            // Update dist[v] only if it is not in sptSet, there is an edge from
            // u to v, and total weight of path from src to v through u is
            // smaller than current value of dist[v]
            if (!sptSet[v] && graph[u][v] && dist[u] != INT_MAX

```

```

        && dist[u]+graph[u][v] < dist[v])
        dist[v] = dist[u] + graph[u][v];
    }

    // print the constructed distance array
    printSolution(dist, V);
}

```

```

// driver program to test above function
int main()
{
    /* Let us create the example graph discussed above */
    int graph[V][V] = {{0, 4, 0, 0, 0, 0, 0, 8, 0},
                       {4, 0, 8, 0, 0, 0, 0, 11, 0},
                       {0, 8, 0, 7, 0, 4, 0, 0, 2},
                       {0, 0, 7, 0, 9, 14, 0, 0, 0},
                       {0, 0, 0, 9, 0, 10, 0, 0, 0},
                       {0, 0, 4, 0, 10, 0, 2, 0, 0},
                       {0, 0, 0, 14, 0, 2, 0, 1, 6},
                       {8, 11, 0, 0, 0, 0, 1, 0, 7},
                       {0, 0, 2, 0, 0, 0, 6, 7, 0}};

    dijkstra(graph, 0);

    return 0;
}

```

Output:

Vertex	Distance from Source
0	0
1	4
2	12
3	19
4	21
5	11
6	9
7	8
8	14

Notes:

- 1) The code calculates shortest distance, but doesn't calculate the path information. We can create a parent array, update the parent array when distance is updated (like [prim's implementation](#)) and use it to show the shortest path from source to different vertices.
- 2) The code is for undirected graph, same dijkstra function can be used for directed graphs also.
- 3) The code finds shortest distances from source to all vertices. If we are interested only in shortest distance from source to a single target, we can break the for loop when the picked minimum distance vertex is equal to target (Step 3.a of algorithm).
- 4) Time Complexity of the implementation is $O(V^2)$. If the input [graph is represented using adjacency](#)

[list](#), it can be reduced to $O(E \log V)$ with the help of binary heap. We will soon be discussing $O(E \log V)$ algorithm as a separate post.

5) Dijkstra's algorithm doesn't work for graphs with negative weight edges. For graphs with negative weight edges, [Bellman-Ford algorithm](#) can be used, we will soon be discussing it as a separate post. Please write comments if you find anything incorrect, or you want to share more information about the topic discussed above.

Hello . I am trying to solve UVa 11631 problem using dijkstra. My input set is as follow;

7 11

0 1 7

0 3 5

1 2 8

1 3 9

1 4 7

2 4 5

3 4 15

3 5 6

4 5 8

4 6 9

5 6 11

* $V = 7$, $E = 11$ << 1st line. From 1st node (0) to last node(6) what should be the MST value. I am getting 22. Can someone check?

Question • 2 months ago

Is there anyway to output the path that was taken to get to the destination?

^ | v • Reply • Share ›

haibo wang • 3 months ago

In the for loop, should the check condition be "count < V;" ?

```
// Find shortest path for all vertices
for (int count = 0; count < V-1; count++)
{
```

```

{
...
}

```

my java code is here <http://javamusician.blogspot.k...>

2 ^ | v • Reply • Share ›

João Dias • 4 months ago

To print the shortest path for each node I used an array, prev[V], in order to keep not only the distance to it but also the previous node in the path.

I initialized all the elements of this array with an impossible value, -1, and then, as suggested, when the distance is updated, the previous node is also updated: prev[v] = u;

Then, to print the path, I used another utility function:

//An utility function to print the minimum path by recursively printing the //previous node, from the destination to the source

```
void printPath(int dest, int prev[]) {
```

```
if (prev[dest] != -1){ //If we are not at the source node  
    printPath(prev[dest], prev);  
    printf(" - ");  
}  
  
printf("%d", dest);  
  
}
```

Vineet Sharma • 9 months ago

why we need to find the minimum distance value of the vertex not included in SPT set???

^ | v • Reply • Share ›

helper → Vineet Sharma • 7 months ago

because the minimum distance from source to that vertex is still not finalized and can change...

If you are curious about why the min. dist. of that path is finalized and how we are sure that we will not find a lower cost path from src to that vertex in future using the unused vertices, you should look at this:

<https://www.cs.auckland.ac.nz/...>

1 ^ | v • Reply • Share ›

Swati • 10 months ago

`dist[u] != INT_MAX && dist[u]+graph[u][v] < dist[v]`

why the first condition is required as even in its absence second condition will take care for INFINITE vertices.

^ | v • Reply • Share ›

Jon Snow → Swati • 8 months ago

Because of possibility of overflow. If we are not checking first condition and simply adding `dist[u]+graph[u][v]` it will overflow as `dist[u]` is initialized to `INT_MAX`. overflow means value of `dist[u]+graph[u][v]` become negative and second condition will always evaluates to true.

1 ^ | v • Reply • Share ›

skal • a year ago

Hi,

if I use : `parent[v] = u, dist[v] = dist[u] + distArr[u][v]`; as described on Notes (1) I only get the latest vertex of the path to destination.

The code is working if I iterate calling the `dijkstra()` from all every source I get all the minimum paths from source to dist. But `parent[v]` only holds the last step of the path!

Any ideas?

5 ^ | v • Reply • Share ›

GaoTong • a year ago

The code is wrong! The test is right, because the special test data.

This is wrong:

```
for (int i = 0; i < V; i++)
```

```
dist[i] = INT_MAX, sptSet[i] = false;
```

It should be:

```
for (int i = 0; i < V; i++){
```

```
dist[i] = (graph[source][i] == 0 ? INT_MAX:graph[source][i]);
```

```
sptSet[i] = false;
```

```
}
```

7 ^ | v • Reply • Share ›

JRa → GaoTong · 10 months ago

Umm, actually if you were to change the code like you mentioned, your FOR loop would be redundant...because on the first iteration, the minDistance() function would return the 0-distance (source) as 'u', and set the adjacent nodes values redundantly.

^ | v · Reply · Share ›

jithin · a year ago

i think the above implementation is taking $O(n^3)$: outer for loop iterating n times , function minDistance : taking $o(n)$ time to compute minimum and inner for loop taking $O(n)$. ie $n*n*n = n^3$

4 ^ | v · Reply · Share ›

prashant jha · a year ago

u can use min heap or rmq for reducing complexity

<http://ideone.com/2gJjz2>

not work for negative edges because here at each step of algorithm we make a vertex permanent that is we have found shortest path upto dat vertex but if it has negative edges there may exist a path shorter than dat length ..so greedy algorithhm dont work there

^ | v · Reply · Share ›

Ankur · 2 years ago

`dist[u] != INF` is a redundant check since `dist[u] == INF` will only be true if it was an isolated node , but than again all values of `graph[u][v]` will be 0 for this node and the condition

`if (!sptSet[v] && graph[u][v] && dist[u] != INT_MAX && dist[u] + graph[u][v] < dist[v])`

will never be true. But since this situation is tackled by checking `graph[u][v]` , so why bothering checking `dist[u] != INF` ?

Nikhil Choudhary · 2 years ago

Problem Statement:-

Consider a data communication network that must route data packets (email or MP3 files, for

example). Such a network consists of routers connected by physical cables or links. A router can act as a source, a destination, or a forwarder of data packets. We can model a network as a graph with each router corresponding to a vertex and the link or physical connection between two routers corresponding to a pair of directed edges between the vertices.

A network that follows the OSPF (Open Shortest Path First) protocol routes packets using

Dijkstra's shortest path algorithm. The criteria used to compute the weight corresponding to a

link can include the time taken

The article was very helpful, thank you. I changed the code so that it is clearer to me (some parts left out):

```
int minDistance(int dist[], bool sptSet[])
{
    int min = INT_MAX, min_index = -1;

    for (int v = 0; v < V; v++)
        if (sptSet[v] == false && dist[v] < min)
            min = dist[v], min_index = v;

    return min_index;
}

void dijkstra(int graph[V][V], int src)
{
    //init code
```

[see more](#)

^ | v • Reply • Share ›

viki • 2 years ago

I think "&& dist[u] != INT_MAX" is redundant check.

^ | v • Reply • Share ›

Ashish Tilokani → viki • a year ago

Its used because the next condition is that of $\text{dist}[u] + \text{graph}[u][v] < \text{dist}[v]$ which can cause overflow as `Int` type cannot store more than `INT_MAX` and the LHS can be `INT_MAX + any positive integer`

2 ^ | v • Reply • Share ›

Kailash Gupta • 2 years ago

Should not we break the outer for loop when `dist[u] == INT_MAX` ?Because that means no node has left which can be reached from source node

^ | v • Reply • Share ›

Tan Syh Ren • 2 years ago

the graph matrix seems to mismatch with the illustration
